

SHOCK INITIATION MEASUREMENTS USING MULTIPLE SAMPLES & INSTRUMENTED WITH PDV

Rick Gustavsen, Brian Bartram, Nate Sanchez,
Shock and Detonation Physics Group, DE-9
Los Alamos National Laboratory, Los Alamos, NM 87545

4th Annual PDV Workshop
November 5 & 6, 2009
University of Texas, Austin

Approved for public release. Distribution unlimited.

Experiment we hoped to replicate using PDV

Gustavsen, Sheffield, and Alcon, J. Appl. Phys., 99, 114907 (2006)

Why PDV?

Samples came in form of 25 mm diameter rods. Magnetic gauge experiments require 50 mm diameter cylinders. We still wanted measurements at multiple depths.

Samples were cut as shown to look for possible orientation effects

Disks

Slabs

Plate impact experiment

1550 nm PMMA window correction factor. (I used 1.00)

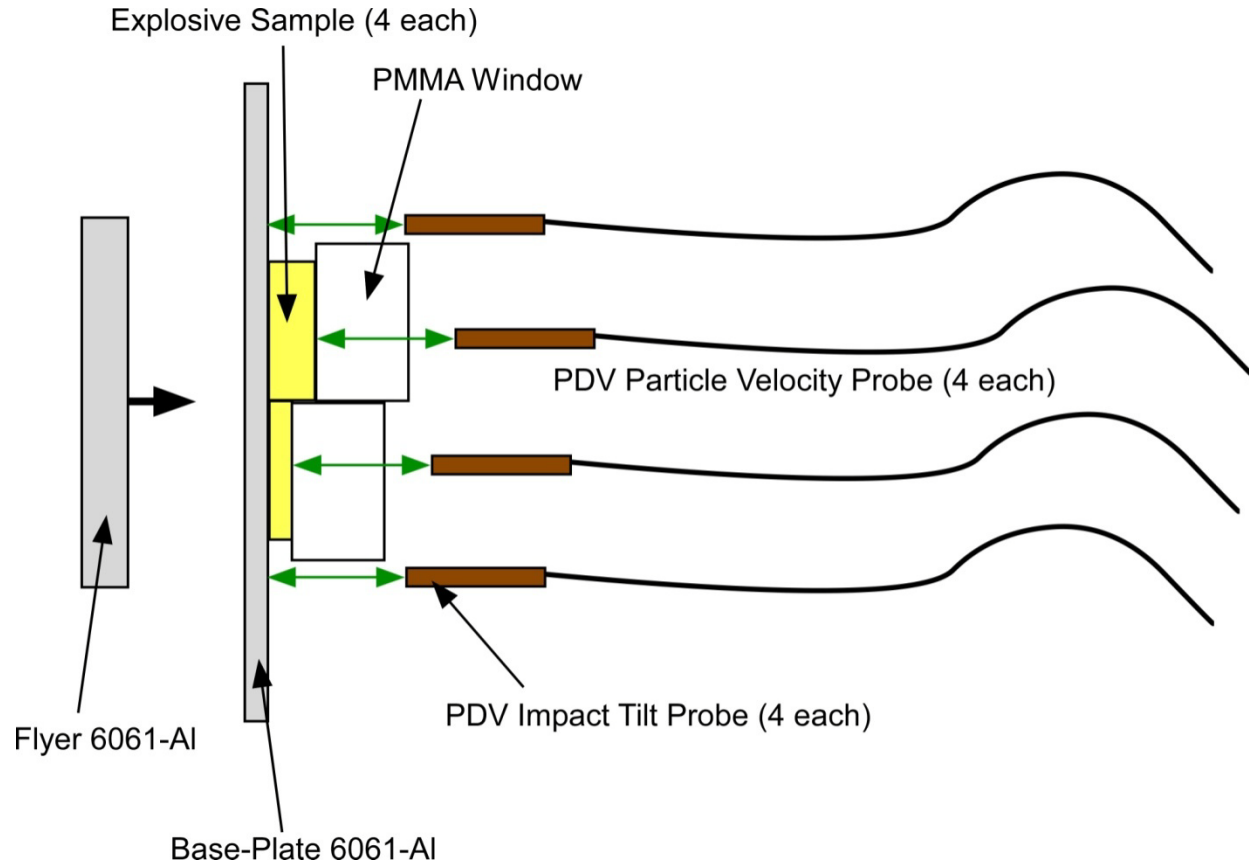

Shot #	Apparent Velocity (km/s)	True Velocity (km/s)	Correction factor
2s-401	1.584(7)	1.572(8)	1.008
AWE-1	0.2059	0.2192	0.94
AWE-2	0.2121	0.2179	0.97
AWE-3	0.4457	0.456	0.977

AWE data from Pete Keightley

Correction factors for 514 nm 1.00, J. Wackerle, SPIE (1987)

Correction factor 532 nm 0.99, L. Barker, supplied with VALYN VISAR

Plate impact experiment

Impact Experiment – Photos (shot 2s-405)

Note – AC Photonics collimating probes, 8° wedges

Impact Experiment – Photos (Shot 2s-412)

Note Oz-optics 21 mm focusing probe

Optical layout and Interferometer setup

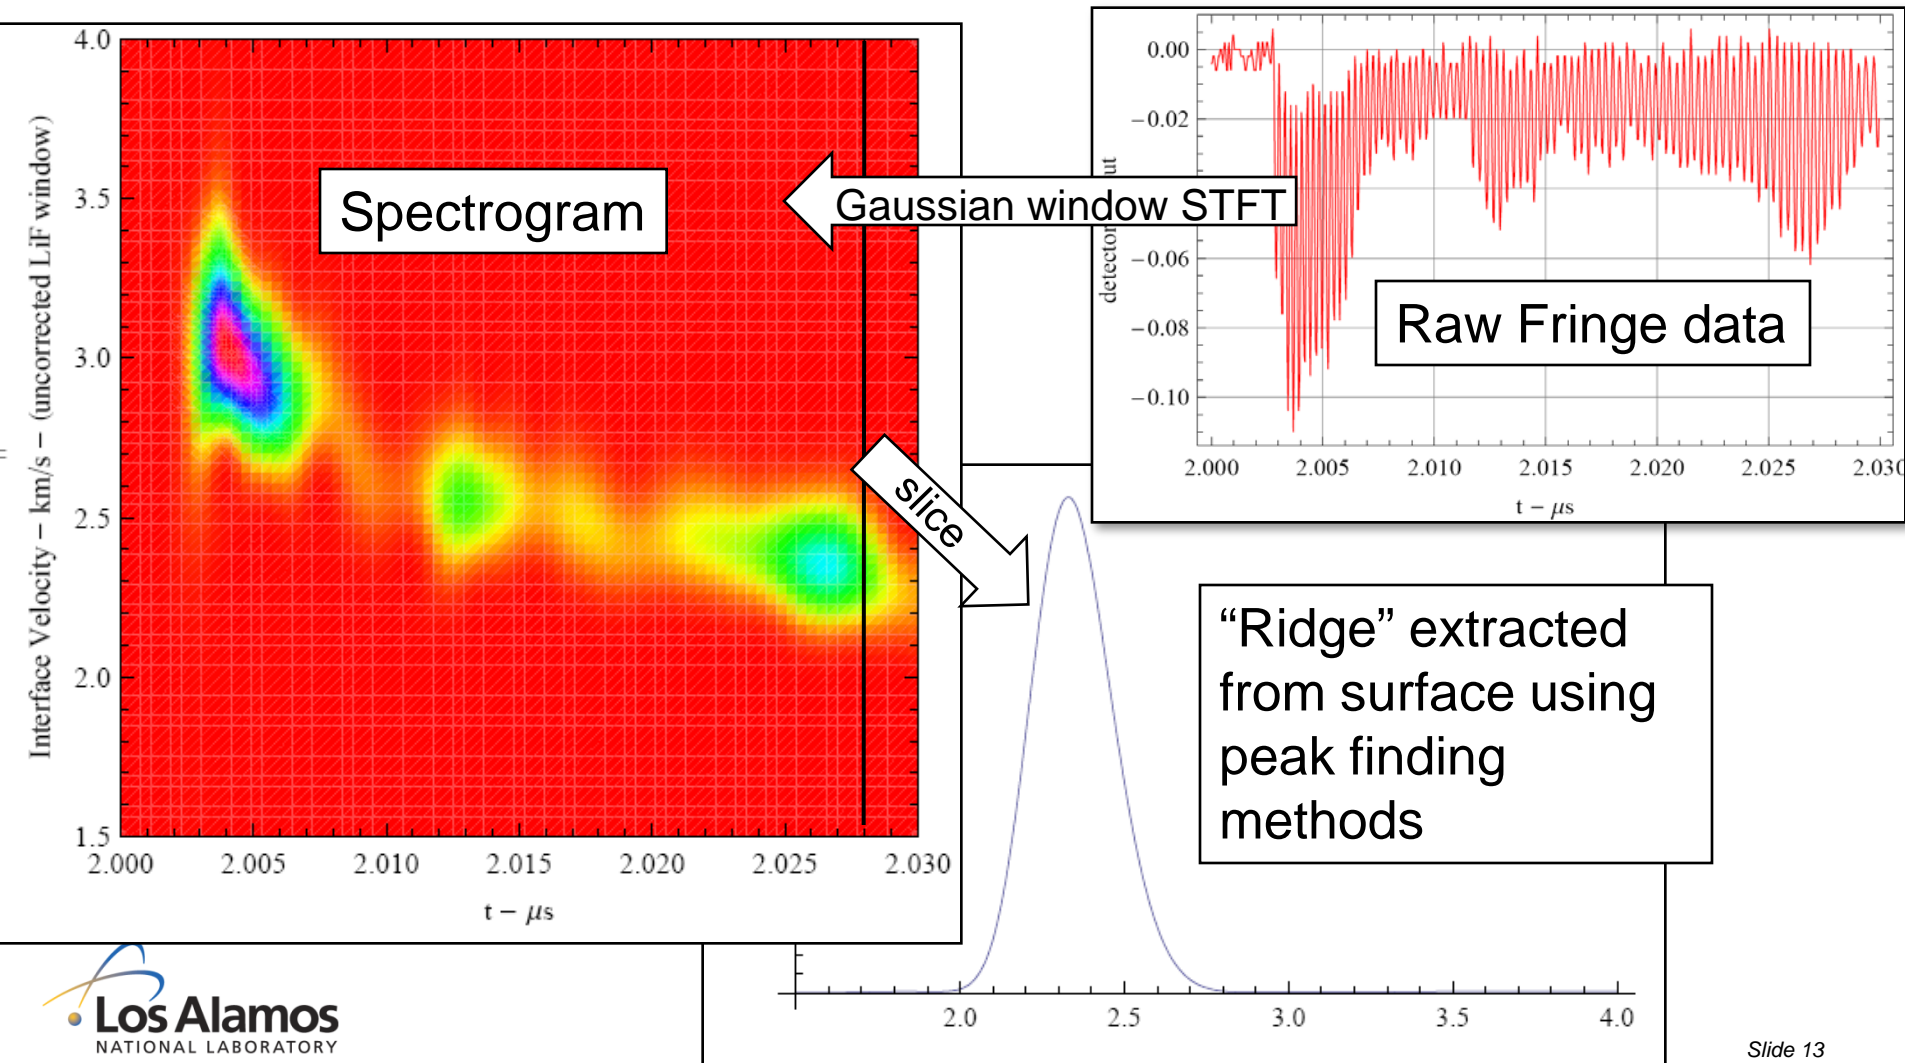

Raw Data (example)

Spectrogram (example)

Time - Frequency Analysis: “Time resolution” defined by FFT window size.

Raw data and Windowed data

Fourier transformed data

After interpolation with 3rd order spline.

Interpolation is actually in both time and frequency directions.

Another method for finding the peak

Frequency Shift

$$\exp(i2\pi\omega t) f(t) \rightarrow F(s - \omega)$$

Peak at 42

Fractional Fourier Transform

$$F_n = \sum_{k=0}^{N-1} f_k \exp(ib2\pi nk / N)$$

$$freq. = [42 - 2] - (203 - 1) \left(\frac{2}{300} \right) = 41.347$$

Shift

Fraction, b

Shot 2s-413 data prior to correcting for tilt – raw time

Shot 2s-413 corrected for tilt and time origin

- Impact velocity 2.138 km/s
- Impact Pressure ~ 13.62 GPa
- Tilt ~ 11 mrad. Top first.
- Nominal distance to detonation 6.2 mm

Four experiments, different materials, same input, different sensitivity

Conclusions

- Methods for measuring wave-profiles from multiple samples presented.
- Wave evolution displayed, similar to that seen in embedded gauge measurements.
- Base-plate and sample signals multiplexed onto same detector. Signals must be separated in time and/or space.
- Tilt corrections are important in this type of experiment.
